Ejercicio 1

En este ejercicio se busca integrar los conocimientos aprendidos a lo largo del curso. Para ello se solicita realizar lo siguiente:

- Completar la derivación de la distribución de Marcenko-Pastur, partiendo de las notas de clase. Sea los más claro posible, sin omitir ningún detalle algebraico (puede escanearlo.)

- b. Reproduzca la figura 14.1 del libro seguido en este módulo (*Introduction to Random Matrices*, G. Livan et. al.), bajo las mismas condiciones y parámetros (compruebe que $p > 0.05$ en el test de Kolmogorov-Smirnov).
- c. Descargue las series de tiempo que componen el índice bursátil Standard & Poor's 500. Utilizando una periodicidad semanal durante los últimos 10 años (Enero 2008 a la fecha).

Descargamos los datos en tiempo real y graficamos algunas de las series. Utilizamos los tickers de las empresas que contribuyen al S&P500 previamente de <https://mx.investing.com/indices/investing.com-us-500-components>.

```
diferencia <- today() - ymd('2008-01-01')
fecha <- as.numeric(diferencia)
today() - days(fecha) #chechar fecha de inicio
```

```
## [1] "2008-01-01"
```

```
first.date <- Sys.Date() - fecha #actualización en tiempo real
last.date <- Sys.Date()
freq.data <- 'weekly' # frecuencia semanal
```

```
# lectura de tickerts
```

```
Componentes_Investing_com_United_States_500 <- read_csv("Componentes Investing.com United States 500.csv",
#https://mx.investing.com/indices/investing.com-us-500-components los nombres de las empresas
```

```
tickers <- Componentes_Investing_com_United_States_500$Símbolo
```

```
companias <- BatchGetSymbols(tickers = tickers,
                             first.date = first.date,
                             last.date = last.date,
                             freq.data = freq.data,
                             do.complete.data = FALSE) #sihay nulos los descartamos
```

```
##
```

```

class(serie) <- 'data.frame'
```

```
serie %>% select(ticker, ref.date, price.close) -> serie# era open o close ?
```

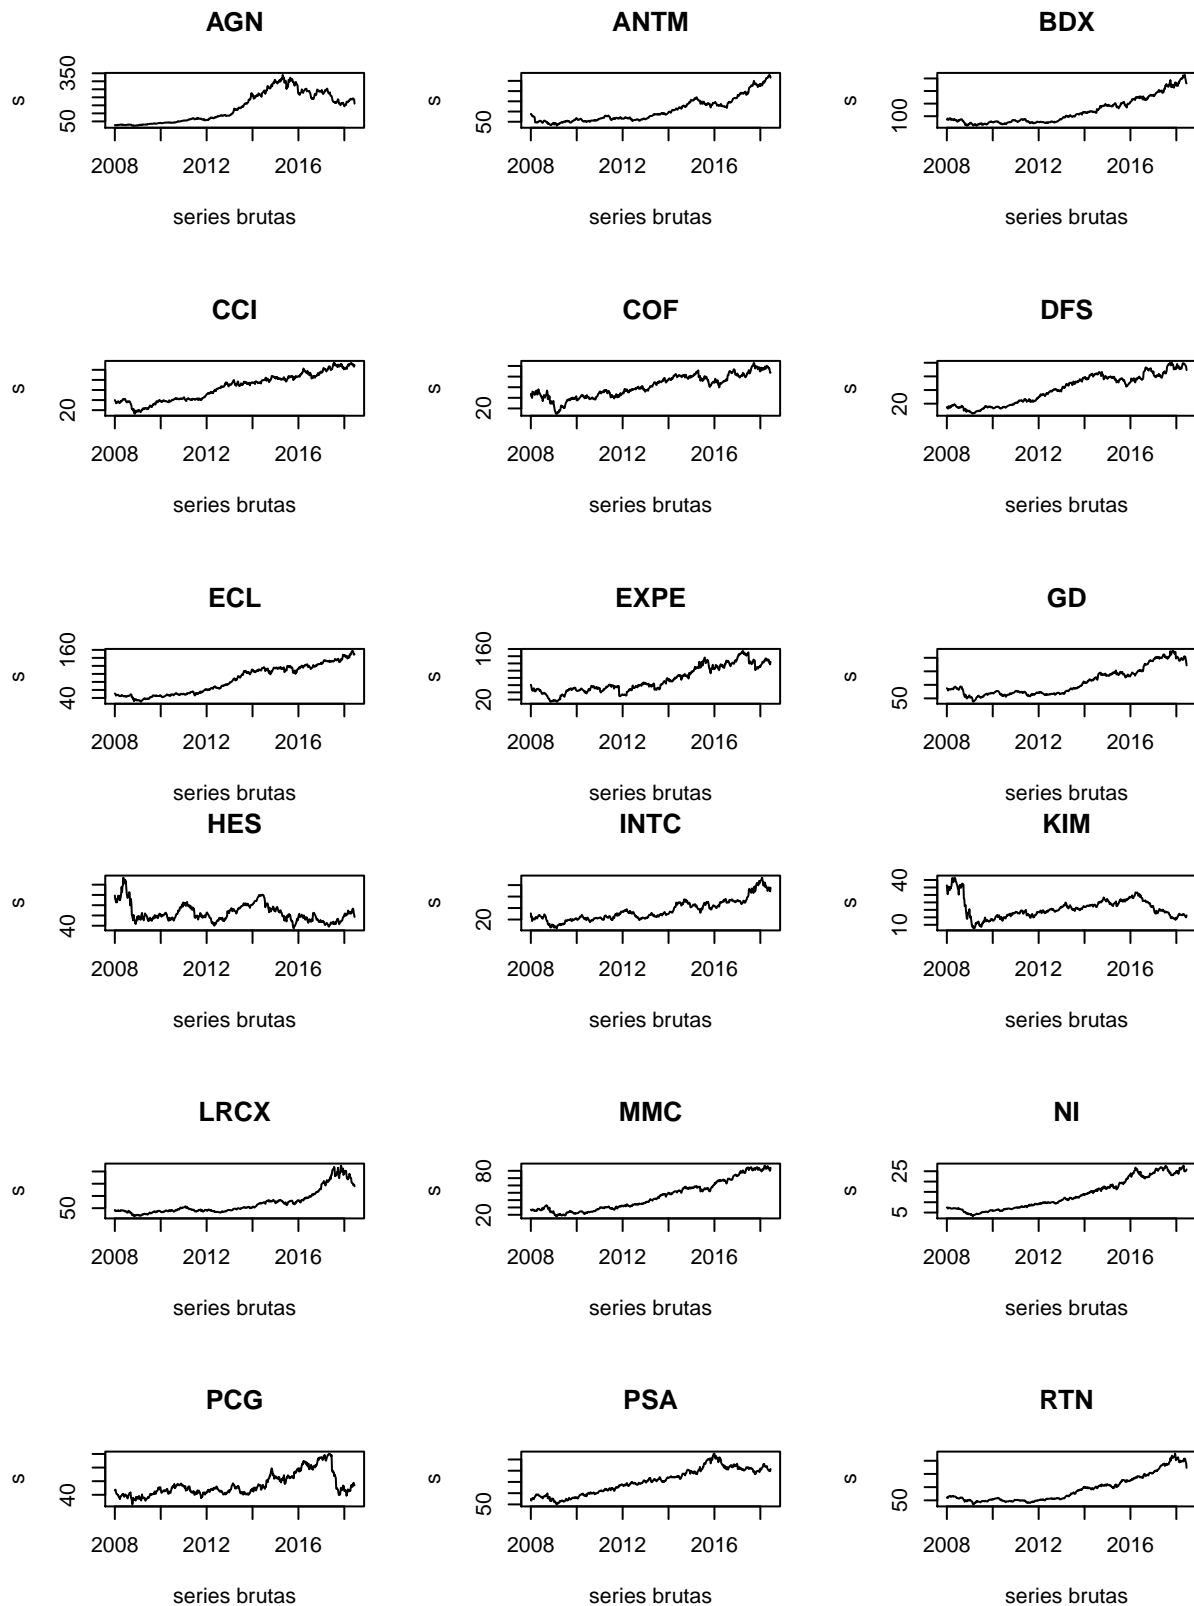

- d. Aplique las transformaciones necesarias (aprendidas en el módulo de series de tiempo) para trabajar las series de tiempo desde el punto de vista estacionario. Deseche las series de los mercados que presentan problemas.

Se procedió a aplicar la transformación logaritmo para disminuir la varianza de las series originales, también se aplicaron técnicas para eliminar la estacionalidad en las pocas series que la presentan. El resultado es un conjunto de datos (de dimensiones 565,449) donde las observaciones son semanas registradas y las columnas las empresas que reportan su indicador de cierre. También se determinó un resago de 8 para todas las series para estacionalizar las series, la prueba de Anderson Darling descarta que tengamos raíces unitarias.

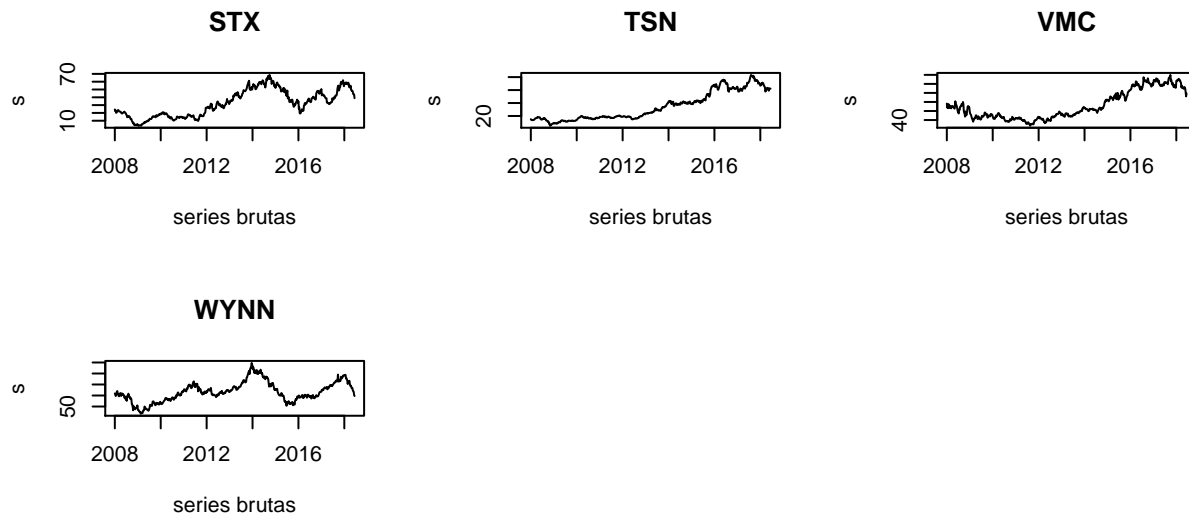

```
SP500 <- BatchGetSymbols(tickers = "^GSPC",

e. Determine el número de componentes significativos adecuando un test derivado de la distribución de Marcenko-Pastur.

En vista de que conocemos la distribución asintótica de Marchenko Pastur, el criterio que determinamos se construye contemplando únicamente los valores propios que son mayores a la esperanza de la distribución, para ello la estimamos con una muestra 10 veces más grande que el número de registros de nuestro conjunto de datos.

```

```

- f. Aplique regresión por componentes principales utilizando el número de componentes sugeridos por el resultado de matrices aleatorias y compare el resultado utilizando el criterio del 80% de la varianza. Se busca predecir el valor de apertura del índice S&P500 el lunes por la mañana a través de los 500 mercados que lo componen.

Para poder medir el error en porcentaje utilizamos el SMAPE cuyo rango es [0,100] donde 0 es un error de 0% (predicción perfecta) y 100 una predicción totalmente errónea. También utilizamos el error promedio sobre las predicciones del año 2008. Los resultados son de 86% aprox. en ambos casos.

```

g. Grafique la efectividad del pronóstico durante este año.

p1

p2

Pronostico para 2018,SP800, criterio 80% varianza y PCR

- h. ¿Cómo mejoraría el pronóstico? si obtiene un promedio en la efectividad mayor al 50% gana puntos extras en proporción a como este valor se acerque al 100% (Puede explorar otros métodos de pronóstico en busca de mayor efectividad, pero siempre contrastando con el criterio de matrices aleatorias).

En vista de que estamos trabajando con configuraciones de datos de dimensionalidad mediana, consideramos un método de regresión, PLS, que a su vez no requiere de supuestos distribucionales, reduce dimensionalidad y podemos utilizar el criterio de Marchenko Pastur como cota superior para evaluar el número de componentes (a.k.a variables latentes de PLS) y disminuir el tiempo de cómputo. Los resultados mejoran a los anteriores alcanzando una precisión de 85%

```
